Takes a lot of things & squeezes them to

Aggregate Functions one single answer
Imagine you have a large basket of apples.

Instead of looking at each apple on by one, an **AGGREGATE FUNCTION** is like a magic trick that looks at the entire basket and tells you one big answer

↳ Summarizes data

↳ Consolidates data

↳ Performs calculations on multiple rows of specific columns & returns a single value per group

① **COUNT()**: Counts **HOW MANY** apples are in the basket (ID)

② **SUM()**: Adds up total to see how much they weigh together (REV)

③ **MAX()**: Finds the biggest apple in the basket. / Largest value in the column.

④ **MIN()**: Finds the smallest apple / value in the column

⑤ **Avg()**: Finds medium-sized apple.

GROUP BY statement

gender, race

SELECT categorical column,

aggregated - Function (column) AS

descriptive - column - name. numerical column

FROM table - name

GROUP BY categorical column;

↳ group by column that is NOT

aggregated

HAVING statement

◦ Imagine you & your friends are putting all your toy cars into boxes based on color.

First, you put all the **red cars** in one box, the **blue cars** in another and the **green cars** in the third box (This is GROUP BY)

◦ Now you want to count how many cars are in each box

Red = 6 Blue = 1 Green = 5

But you only want to play with boxes that have a lot of cars inside. You tell your friends:

"I only want the boxes that have **MORE**."

"THAN 3 CARS!" = HAVING statement

◦ Looks at your finished boxes & throws away ones that don't fit the rule.
